For elastic design, each of the members in the structure must have a design bending moment capacity ( $M_s$ ) greater than the design moment ( $M^*$ ) obtained from an elastic analysis. The bending moment capacity, calculated by including the appropriate capacity factor  $\gamma$  and other design considerations, is often used to represent the plastic moment  $M_p$  in plastic analysis.

Elastic analysis is mostly preferred for the concrete structures. In elastic analysis equilibrium, equations are used to simplify the structures. Three types of equation are given as below. • Summation of vertical forces should be zero. • Summation of horizontal forces should be zero. • The moment about any point should be zero. The design method of working stress based approach is based on the elastic analysis concept.

Elastic design is carried out by assuming that at design loads structures behave in a linearly elastic manner. An elastic analysis is performed by applying the design loads and required internal forces in the structural elements (members and connections) are determined and adequate design strength is provided. Since the element forces are

## PLASTIC VERSUS ELASTIC DESIGN OF STEEL STRUCTURES

In the elastic analysis of circular plates, it is convenient to express the governing differential equation in polar coordinates, even though rectangular (Cartesian) coordinates can be used (as applied in this article). This can be readily accomplished by a coordinate transformation and can be found in many pieces of literature.

The method consists of a series of elastic analyses, each of which represents the formation of a plastic hinge in the structure. Results for each elastic analysis are transferred to a spreadsheet from which the location for the formation of a plastic hinge and the corresponding increment of loading in terms of the common load factor can be obtained.

Chapter 9: Column Analysis and Design Introduction Columns are usually considered as vertical structural elements, but they can be positioned in any orientation (e.g. diagonal and horizontal compression elements in a truss). Columns are used as major elements in trusses, building frames, and sub-structure supports for bridges (e.g. piers).

## Chapter 9: Column Analysis and Design

The elastic method of design assumes that a frame will become useless as soon as yield stress is reached. The working stress is, therefore, kept much below the yield stress. The design so produced gives a structure of unknown ultimate strength. The elastic methods of analysis are also very cumbersome, specially for redundant frames.
